

Hi Dev team, Ainsley recommended I should drop this here for you to answer - Yesterday's blog post mentions a key management node will be used in the upcoming testing but it's not clear if this node is only part of your internal test network or is part of the actual testnet that will be coupled to ethereum in the next release. Can the team clarify this? When I hear key management node I hear centralized component. It sounds a little like the principal node used in the previous docker testnet which is not supposed to be needed in Discovery. So will this be hitting main net or is it only a node used in your internal testing?

Cheers,

Fergal
