

Hey sirs,

I think we should get started on the conversation of reducing trust towards relayers. They are low hanging fruits with relatively little overhead that can benefit not only the proposer-builder-relayer trifecta, but the network itself. I've got one going, and it basically leverage zero-knowledge encryption and participants incentives to reduce trust assumptions toward Optimistic relays.

Here is the [link](#), it includes code and a more detailed explanation of the problematic as well as the upside of the proposed approach. Sorry for pointing to my repo, I actually had the write-up in here, but as a new forum member I can only post two links!

See yall in the mempool, in here, or hit me [there](#).
