

hey,

i had a question concerning your last thread on twitter Sreeram, concerning the amount of stake that could be slashed, is it defined by eigenlayer or the service building on eigenlayer ?

on a service, i was thinking of implementing the same type of slashing that we can find on ethereum aka slashing the whole stake if many validators try to collude and make an attack or slashing only 1 eth if it is a mistake from one validator ... from my understanding of your thread, the max slash possible on eigenlayer would be half of the stake but maybe im wrong so would love to know more about it !

cheers
