

Hey folks!

The migration's going on right now, but I still wanted to get the discussion started in regards to implementing a Uniswap-V2 market on Aave. As of now, we can deposit our UNI-V1 tokens in their respective market.

Anyway, I was wondering if anyone more well-versed in the intricacies of Aave's contract code and limitations could answer these two questions:

1. Does the implementation of different markets (like what was done with UNI-V1 and soon SETs) have a negative impact on the gas fees (as is the case with each additional added collateral) of all Aave markets?
2. Are there technical limitations in regards to the structure of the UNI-V2 tokens that could cause an issue with Aave integration; in other words, Is it possible?

Lastly, if this integration would be deemed more beneficial than detrimental, what do you guys think the consequences of implementing UNI-V2 tokens as collateral on Aave would be?

Thanks in advance for your input!
