

Using User-hosted Secrets in Requests

This tutorial shows you how to send a request to a Decentralized Oracle Network to call the [Coinmarketcap API](#) . After [OCR](#) completes offchain computation and aggregation, it returns the BTC/USD asset price to your smart contract. Because the API requires you to provide an API key, this guide will also show you how to encrypt, sign your API key, and share the encrypted secret offchain with a Decentralized Oracle Network (DON).

The encrypted secrets are never stored onchain. This tutorial uses the threshold decryption feature. This tutorial shows you how to share encrypted secrets offchain with a Decentralized Oracle Network (DON) using a storage platform such as AWS S3, Google Drive, IPFS, or any other service where the DON can fetch secrets via HTTP. Read the [Secrets Management page](#) to learn more.

Read the [Using User-hosted \(gist\) Secrets in Requests](#) tutorial before you follow the steps in this example. This tutorial uses the same example but with a slightly different process:

1. Instead of relying on storing the encrypted secrets on gist, you will host your encrypted secrets on AWS S3.
2. Include the encrypted secrets in an `offchain-secrets.json` file.
3. Host the secrets file offchain (AWS S3).
4. Encrypt the S3 HTTPs URL .
5. Include the encrypted URL in your Chainlink Functions request.

caution

Chainlink Functions is still in BETA. The use of secrets in your requests is an experimental feature that may not operate as expected and is subject to change. Use of this feature is at your own risk and may result in unexpected errors, possible revealing of the secret as new versions are released, or other issues.

note

Chainlink Functions is a self-service solution. You must ensure that the data sources or APIs specified in requests are of sufficient quality and have the proper availability for your use case. You are responsible for complying with the licensing agreements for all data providers that you connect with through Chainlink Functions. Violations of data provider licensing agreements or the [terms](#) can result in suspension or termination of your Chainlink Functions account.

Prerequisites

note

You might skip these prerequisites if you have followed one of these [guides](#) . You can check your subscription details (including the balance in LINK) in the [Chainlink Functions Subscription Manager](#) . If your subscription runs out of LINK, follow the [Fund a Subscription](#) guide.

Set up your environment

You must provide the private key from a testnet wallet to run the examples in this documentation. Install a Web3 wallet, configure [Node.js](#) , clone the [smartcontractkit/smart-contract-examples](#) repository, and configure a `.env` file with the required environment variables.

Install and configure your Web3 wallet for Polygon Mumbai:

1. [Install Dero](#) so you can compile and simulate your Functions source code on your local machine.
2. [Install the MetaMask wallet](#) or other Ethereum Web3 wallet.
3. Set the network for your wallet to the Polygon Mumbai testnet. If you need to add Mumbai to your wallet, you can find the chain ID and the LINK token contract address on the [LINK Token Contracts](#) page.
4. [Polygon Mumbai testnet and LINK token contract](#)
5. Request testnet MATIC from the [Polygon Faucet](#) .
6. Request testnet LINK from [faucets.chain.link/mumbai](#) .

Install the required frameworks and dependencies:

1. [Install the latest release of Node.js 20](#) . Optionally, you can use the [nvm package](#) to switch between Node.js versions with `nvm` use 20.

Note: To ensure you are running the correct version in a terminal, type `node -v`.

`node -v` node-vv20.9.0 2. In a terminal, clone the [smart-contract-examples](#) repository and change directories. This example repository imports the [Chainlink Functions Toolkit NPM package](#) . You can import this package to your own projects to enable them to work with Chainlink Functions.

`git clone https://github.com/smartcontractkit/smart-contract-examples.git` & `cd ./smart-contract-examples/functions-examples/` 3. Run `npm install` to install the dependencies.

`npm install` 4. For higher security, the examples repository encrypts your environment variables at rest.

1. Set an encryption password for your environment variables.

`npx env-enc set -pw` 2. Run `npx env-enc set` to configure a `.env` file with the basic variables that you need to send your requests to the Polygon Mumbai network.

- POLYGON_MUMBAI_RPC_URL: Set a URL for the Polygon Mumbai testnet. You can sign up for a personal endpoint from [Alchemy](#) , [Infura](#) , or another node provider service.
- PRIVATE_KEY: Find the private key for your testnet wallet. If you use MetaMask, follow the instructions to [export a Private Key](#) . Note: Your private key is needed to sign any transactions you make such as making requests.

`npx env-enc set`

Configure your onchain resources

After you configure your local environment, configure some onchain resources to process your requests, receive the responses, and pay for the work done by the DON.

Deploy a Functions consumer contract on Polygon Mumbai

1. [Open the FunctionsConsumerExample.sol contract](#) in Remix.

[Open in Remix](#) What is Remix? 2. Compile the contract. 3. Open MetaMask and select the Polygon Mumbai network. 4. In Remix under the Deploy & Run Transaction tab, select Injected Provider - MetaMask in the Environment list. Remix will use the MetaMask wallet to communicate with Polygon Mumbai. 5. Under the Deploy section, fill in the router address for your specific blockchain. You can find both of these addresses on the [Supported Networks](#) page. For Polygon Mumbai, the router address is `0x6E2dc0F9DB014aE19888F539E59285D2Ea04244C`. 6. Click the Deploy button to deploy the contract. MetaMask prompts you to confirm the transaction. Check the transaction details to make sure you are deploying the contract to Polygon Mumbai. 7. After you confirm the transaction, the contract address appears in the Deployed Contracts list. Copy the contract address.

Create a subscription

Follow the [Managing Functions Subscriptions](#) guide to accept the Chainlink Functions Terms of Service (ToS), create a subscription, fund it, then add your consumer contract address to it.

You can find the Chainlink Functions Subscription Manager at [functions.chain.link](#) .

Tutorial

This tutorial is configured to get the BTC/USD price with a request that requires API keys. For a detailed explanation of the code example, read the [Examine the code](#) section.

You can locate the scripts used in this tutorial in the [examples/7-use-secrets-urldirectory](#) .

1. Get a free API key from [CoinMarketCap](#) .
2. Run `npx env-enc set` to add an encrypted COINMARKETCAP_API_KEY to your `.env` file.

`npx env-enc set` 3. Prepare the store for your encrypted secrets file.

1. Create a [AWS free tier account](#) .
2. Follow [these steps](#) to create a AWS S3 bucket. Choose a name for your bucket, set ACLs enabled, and turn off Block all public access.

Build Offchain Secrets

1. Encrypt the secrets and store them in the `offchain-secrets.json` file using the `gen-offchain-secrets` script of the `7-use-secrets-url` folder.

\$ node examples/7-use-secrets-url/gen-offchain-secrets.js secp256k1 unavailable, reverting to browser version Encrypted secrets object written to /functions-examples/offchain-secrets.json 2. Follow these [steps](#) to upload the file offchain-secrets.js onto your AWS S3 bucket. 3. To make the file publically accessible without authentication:

1. Find the file in the bucket list, and click on it to open the object overview.
2. Click on the **Permissions** tab to display the **Access control list (ACL)**.
3. Click on **Edit**.
4. Set **Everyone (public access)** Objects read, then confirm. This action makes the object readable by anyone on the internet.
5. Note the object URL.
6. To verify that the URL is publicly readable without authentication, open a new browser tab and copy/paste the object URL in the browser location bar. After you hit **Enter**, the browser will display the content of your encrypted secrets file.
7. Note the URL. You will need it in the following section. For example: `https://cffunctions.s3.eu-north-1.amazonaws.com/offchain-secrets.json`.

To run the example:

1. Open the `filerequest.js`, which is located in the `7-use-secrets-url` folder.
2. Replace the consumer contract address and the subscription ID with your own values.

const secretsUrls=["https://cf-functions.s3.eu-north-1.amazonaws.com/offchain-secrets.json"]// REPLACE WITH YOUR VALUES after running gen-offchain-secrets.js and uploading offchain-secrets.json to a public URL 4. Make a request:

\$ node examples/7-use-secrets-url/request.js secp256k1 unavailable, reverting to browser version Start simulation... Performing simulation with the following versions: deno 1.36.3 (release, aarch64-apple-darwin) v8 11.6.189.12 typescript 5.1.6

Estimate request costs... Duplicate definition of Transfer (Transfer(address,address,uint256,bytes), Transfer(address,address,uint256)) Fulfillment cost estimated to 0.0000000000000215 LINK

Encrypt the URLs..

[illegible]

- Your request is first run on a sandbox environment to ensure it is correctly configured.
- The fulfillment costs are estimated before making the request.
- The AWS S3 URL is encrypted before sending it in the request.
- Your request was successfully sent to Chainlink Functions. The transaction in this example is [0x1af53189bc379740632dd5f9fc295d46d8d41e901b34b787ccfdb7d0692547a](#) and the request ID is `0xd62da69f11c40c08849d2fce7b1f6cabf94683f8dc1313e048d9729812d27b6`.
- The DON successfully fulfilled your request. The total cost was: `0.000038203918015388 LINK`.
- The consumer contract received a response in bytes with a value of `0x00276b9b`. Decoding it offchain to int256 gives you a result: `2583451`.

  }

  To write a Chainlink Functions consumer contract, your contract must import FunctionsClient.sol and FunctionsRequest.sol . You can read the API references FunctionsClient and FunctionsRequest .

```

```
import {FunctionsClient} from "@chainlink/contracts/src/v0.8/functions/dev/v1_0_0/FunctionsClient.sol"; import {FunctionsRequest} from
"@chainlink/contracts/src/v0.8/functions/dev/v1_0_0/libraries/FunctionsRequest.sol"; * Use the FunctionsRequest.sol library to get all the functions needed for building a Chainlink Functions request.
```

```
bytes32 public s_lastRequestId; bytes public s_lastResponse; bytes public s_lastError; * We define theResponseevent that your smart contract will emit during the callback
```

constructor(address router) FunctionsClient(router) * The three remaining functions are:

- `sendRequest` for sending a request. It receives the JavaScript source code, encrypted secrets URLs (in case the encrypted secrets are hosted by the user), DON hosted secrets slot id and version (in case the encrypted secrets are hosted by the DON), list of arguments to pass to the source code, subscription id, and callback gas limit as parameters. Then:
- It uses the `FunctionsRequest` library to initialize the request and add any passed encrypted secrets reference or arguments. You can read the API Reference for [initializing a request](#), [adding user hosted secrets](#), [adding DON hosted secrets](#), [adding arguments](#), and [adding bytes arguments](#).

```

FunctionsRequest.Request memory req; req.initializeRequestForInlineJavaScript(source); if (encryptedSecretsUrls.length > 0) req.addSecretsReference(encryptedSecretsUrls); else if
(donHostedSecretsVersion > 0) { req.addDONHostedSecrets( donHostedSecretsSlotID, donHostedSecretsVersion ); } if (args.length > 0) req.setArgs(args); if (bytesArgs.length > 0)
req.setBytesArgs(bytesArgs); * It sends the request to the router by calling theFunctionsClientsendRequestfunction. You can read the API reference forsending a request . Finally, it stores the request
id ins _lastRequestIDthen return it.

```

s.lastRequestId = sendRequest(req.encodeCBOR(), subscriptionId, gasLimit, jobId); return s.lastRequestId; Note: sendRequest accepts requests encoded in bytes. Therefore, you must encode it

using [encodeCBOR](#) . * sendRequestCBORfor sending a request already encoded inbytes. It receives the request object encoded inbytes, subscription id, and callback gas limit as parameters. Then, it sends the request to the router by calling theFunctionsClientssendRequestfunction.Note: This function is helpful if you want to encode a request offchain before sending it, saving gas when submitting the request. * fulfillRequestto be invoked during the callback. This function is defined inFunctionsClientasvirtual(readfulfillRequest[API reference](#)). So, your smart contract must override the function to implement the callback. The implementation of the callback is straightforward: the contract stores the latest response and error ins_lastResponseands_lastErrorbefore emitting theResponseevent.

```
s_lastResponse = response; s_lastError = err; emit Response(requestId, s_lastResponse, s_lastError);
```

JavaScript example

source.js

The JavaScript code is similar to the[Using Secrets in Requests](#) tutorial.

gen-offchain-secrets.js

This explanation focuses on the[gen-offchain-secrets.js](#) script and shows how to use the[Chainlink Functions NPM package](#) in your own JavaScript/TypeScript project to encrypts your secrets. After encryption, the script saves the encrypted secrets on a local file,offchain-secrets.json. You can then upload the file to your storage of choice (AWS S3 in this example).

The script imports:

- [path](#) and [fs](#) : Used to read the[source file](#) .
- [ethers](#) : Ethers.js library, enables the script to interact with the blockchain.
- [@chainlink/functions-toolkit](#): Chainlink Functions NPM package. All its utilities are documented in the[NPM README](#) .
- [@chainlink/env-enc](#): A tool for loading and storing encrypted environment variables. Read the[official documentation](#) to learn more.

The primary function that the script executes isgenerateOffchainSecretsFile. This function can be broken into three main parts:

- Definition of necessary identifiers:
- routerAddress: Chainlink Functions router address on Polygon Mumbai.
- donId: Identifier of the DON that will fulfill your requests on Polygon Mumbai.
- secrets: The secrets object.
- Initialization of etherssignerandproviderobjects. The Chainlink NPM package uses the signer to sign the encrypted secrets with your private key.
- Encrypt the secrets:
- Initialize aSecretsManagerinstance from the Chainlink Functions NPM package.
- Call theencryptSecretsfunction from the created instance to encrypt the secrets.
- Use thefslibrary to store the encrypted secrets on a local file,offchain-secrets.json.

request.js

This explanation focuses on the[request.js](#) script and shows how to use the[Chainlink Functions NPM package](#) in your own JavaScript/TypeScript project to send requests to a DON. The code is self-explanatory and has comments to help you understand all the steps.

The script imports:

- [path](#) and [fs](#) : Used to read the[source file](#) .
- [ethers](#) : Ethers.js library, enables the script to interact with the blockchain.
- [@chainlink/functions-toolkit](#): Chainlink Functions NPM package. All its utilities are documented in the[NPM README](#) .
- [@chainlink/env-enc](#): A tool for loading and storing encrypted environment variables. Read the[official documentation](#) to learn more.
- [../abi/functionsClient.json](#): The abi of the contract your script will interact with.Note: The script was tested with this[FunctionsConsumerExample contract](#) .

The script has two hardcoded values that you have to change using your own Functions consumer contract and subscription ID:

```
constconsumerAddress="0x8dFf78B7EE3128D00E90611FBED20A71397064D9"// REPLACE this with your Functions consumer addressconstsubscriptionId=3// REPLACE this with your subscription ID
```

The primary function that the script executes ismakeRequestMumbai. This function can be broken into six main parts:

- Definition of necessary identifiers:
- routerAddress: Chainlink Functions router address on Polygon Mumbai.
- donId: Identifier of the DON that will fulfill your requests on Polygon Mumbai.
- explorerUrl: Block explorer url of Polygon Mumbai.
- source: The source code must be a string object. That's why we usefs.readFileSyncto readsource.jsand then calltoString()to get the content as astringobject.
- args: During the execution of your function, These arguments are passed to the source code. Theargsvalue is["1", "USD"], which fetches the BTC/USD price.
- secrets: The secrets object.Note: Because we are sharing the URL of the encrypted secrets with the DON, thesecretsobject is only used during simulation.
- secretsUrls: The URL of the encrypted secrets object.
- gasLimit: Maximum gas that Chainlink Functions can use when transmitting the response to your contract.
- Initialization of etherssignerandproviderobjects. The signer is used to make transactions on the blockchain, and the provider reads data from the blockchain.
- Simulating your request in a local sandbox environment:
- UsesimulateScriptfrom the Chainlink Functions NPM package.
- Read theresponseof the simulation. If successful, use the Functions NPM packagedecodeResultfunction andReturnTypenum to decode the response to the expected returned type (ReturnType.uint256in this example).
- Estimating the costs:
- Initialize aSubscriptionManagerfrom the Functions NPM package, then call theestimateFunctionsRequestCostfunction.
- The response is returned in Juels (1 LINK = 10**18 Juels). Use theethers.utils.formatEtherutility function to convert the output to LINK.
- Encrypt the secrets, then create a gist containing the encrypted secrets object. This is done in two steps:
- Initialize aSecretsManagerinstance from the Functions NPM package, then call theencryptSecretsfunction.
- Call theencryptedSecretsUrlsfunction of theSecretsManagerinstance. This function encrypts the secrets URL.Note: The encrypted URL will be sent to the DON when making a request.
- Making a Chainlink Functions request:
- Initialize your functions consumer contract using the contract address, abi, and ethers signer.
- Call thesendRequestfunction of your consumer contract.
- Waiting for the response:
- Initialize aResponseListenerfrom the Functions NPM package and then call thelistenForResponseFromTransactionfunction to wait for a response. By default, this function waits for five minutes.
- Upon reception of the response, use the Functions NPM packagedecodeResultfunction andReturnTypenum to decode the response to the expected returned type (ReturnType.uint256in this example).
