

Non-Tokenized

Particular DeFi actions do not give you a token associated to your interaction with their protocol. For example, depositing on [liquity\(opens in a new tab\)](#) does not give you a token representing your cdp, similarly with [aave\(opens in a new tab\)](#) when you borrow you do not get a tokenized position representing your state.

These stateful interactions are associated with the address whether that is an [EOA Address](#) or [Contract Address](#) .
