

What do you mean exactly? There are always some missing targets (in the non-nomi targets). Nothing new there – unless targets that used to be there for some rows disappeared or there was just a massive amount of targets missing. I update weekly to get the new eras from the validation set that have had their targets added (I only am interested in eras with both 20d & 60d targets). As part of this process, I double-check that no previous era that I've already saved/processed has any changes. The data has always passed this check – no row has ever changed, no target (once added) has ever disappeared, and no missing target (once all the targets around it have been filled-in) has ever gotten filled-in later. But some targets are just missing, yeah. (But it was known and announced that some would be when they started generating multiple targets.)

And I just re-checked the training set – nothing has changed.
