

I'm looking at the omg plasma code and am wondering what happens if a validator creates a transaction where the inputs and outputs don't add up. i.e. Creates a transaction where it creates money of out thin air.

I can't seem to figure out how this problem is prevented? I would guess that the RootChain.sol contract check for tx validity before a withdraw is allowed?

Sorry if the answer is obvious, but I cant seem to figure it out.
