

Awesome post!

I could see a scenario where you purposely fill the IL with as many low value transactions as you can to limit the rewards of other validators. a) how do you ensure the IL transactions are paying the appropriate fee for a block (or could you just stuff it with 0 gas txns?) or b) how do prevent just filling up the IL with useless things so other validators don't have as much space to get MEV or higher value transactions?

Also, I saw Justin's talk on splitting out the attester and proposer roles for MEV auctions. Why not have attesters be in charge of the inclusion list since the proposer role in general seems to be centralizing like the builder one?
