

The reason it is “projected” is because it is just the current estimate of what it is going to be at round resolution, which isn’t until 4 weeks after the start date. Basically, everyday your model is checked against the current state of things and you are shown the corr/mmc/payout stats based on that. But only the last day – 4 weeks, 20 trading days later – actually matters and the payout for the last day only will be your actual payout. Everything before is just something to look at. And the scores can change quite significantly over that time – the scores on the first few days or week of a round don’t mean much at all. (But if those 90%+ percentages hold up, those are very good scores indeed. What it is “good” on an absolute level changes from round to round, but obviously if you are up in the 90 percentiles you are killing it.)
