

[Holochain](#) is a framework for distributed apps that has an agent-centric approach. My initial impression of it after browsing its website, reading some of the white paper, some of the [FAQs](#), and [this blog post on mutual credit cryptocurrencies](#) is that it looks better than Ethereum, providing a simpler, more intuitive approach to solving the scalability problem without compromising the scalability-decentralization-throughput trilemma, unless you really need universal consensus / data as an absolute truth, rather than data as a shared perspective, which corresponds to being able to use fiat currencies or tokens, including crypto fiat currencies like ETH and all other blockchain currencies, or tokens pegged to national fiat currencies or other assets.

I made a post about Holochain previously, but it was deleted due to being too spammy, so this is another one.
