

The interval between eras in the train & validation datasets is weekly, always (it is the weekend round) – the live weekday rounds never make it into those files. So each era starts a week after the previous one. The duration of each is a function of the target(s) you are using because that determines how many others are overlapping and “sharing” in that same target, either 20day (4 weeks) or 60day (12 weeks). (Of course we are scored on a 20d target for live rounds.)
