

Connecting to a Cluster with the Solana CLI

See [Solana Clusters](#) for general information about the available clusters.

Configure the command-line tool

You can check what cluster the Solana command-line tool (CLI) is currently targeting by running the following command:

`solana config get` Usesolana config set command to target a particular cluster. After setting a cluster target, any future subcommands will send/receive information from that cluster.

For example to target the Devnet cluster, run:

```
solana config set --url https://api.devnet.solana.com
```

Ensure Versions Match

Though not strictly necessary, the CLI will generally work best when its version matches the software version running on the cluster. To get the locally-installed CLI version, run:

```
solana --version
```

 To get the cluster version, run:

`solana cluster-version` Ensure the local CLI version is greater than or equal to the cluster version.[Previous Hardware Wallets in the Solana CLI: Ledger Nano](#) [Next Solana CLI: Staking](#)
