

Looks about right to me. The MM is only available over the time the tournament was running, which is just the more recent few years. It also turns out that most models provide lower corr over this period compared to previous periods. There could be many explanations for why this happens. It's good that your model can out-perform the meta model over this time period but it is the future that is at stake. I can probably find a model that outperforms over this time period as well, but could I have found that model 2 years ago, before we know what we know now?
