The correct way to do stake mode, is for the buyer and seller to agree on a comission rate

. E.g. if the agreed rate is 1%, then the buyer could stake 100 NMR and pay the seller 1 NMR… OR stake 735 NMR and pay the seller 7.35 NMR, and so forth. This gives the smooth scalability, that buyers and sellers will want.

To get the same effect, from "Stake Only, with Limit": the seller would set the price at 1 NMR, and the limit at 100 NMR. Then the seller can only get full value, by staking a whole multiple of 100 NMR, and making the same transaction that many times.

Since 100 NMR would be too much for most prospective buyers, the seller will adjust by also offering the same prediction

at a price of 0.1 NMR, with a stake limit of 10 NMR. And so on, and so forth…

That's the crufty noise, your platform will have to deal with… unless

you provide the natural, intuitively expected comission rate model in the first place.

EDIT: Restrading made a very strong case, that "tiered pricing" will provide the needed flexibility, in some ways even more (like price breaks for higher volume). It's kinda complicated, and my models aren't currently good enough that I need to figure it out yet.
