Validators can significantly help increase Ethereum's resilience by foregoing only a small amount of profit—check out our new [post](#) on the writings website!

Written in collaboration with [@elainehu](#) and [@Hasu](#)

tl;dr:

- A new mev-boost feature allows validators to maximize Ethereum's censorship resistance by building low-MEV blocks locally while still outsourcing the building of high-MEV blocks.

- Using this feature carries an opportunity cost—the price of resilience.

- As most blocks are actually low-MEV, however, forfeiting a little profit goes a long way in increasing resilience!

- This is a breakthrough in the tradeoff between maximizing MEV extraction and maximizing censorship resistance.
