Welcome to the tournament!

To answer that question, let me first call your attention to metic called "meta model control."

That is basically the the "wight" or your contributions to the metamodel on a percentage basis. The larger your stake, the more Numerai will "trust" your predictions as stake size is a measure of your confidence in your own predictions.

So how would that translate to the trades the Numerai is making on the open stock market. Well lets assume Numerai has one billion USD in assets under management (AMU). If my model has 0.0013% control than that roughly represents 1.3 million USD in buying/selling power in the primary market.

To your follow up question we dont know which stocks we are predicting on. We dont need to know.
